Objectives:

- To study the materials used in fabrication of VLSI devices.
- To study the structure of devices and process involved in fabricating different types of VLSI circuits.
Fabrication Materials

Different types of fabrication materials

- **Insulators**
  - High electrical resistance
  - Used for isolation of devices
  - e.g. Silicon dioxide

- **Conductors**
  - Low electrical resistance
  - Used for conducting & formation
  - e.g. Gold & aluminum

- **Semiconductors**
  - Electrical resistivity at room temp.
  - Used for formation of devices
  - e.g. Silicon
Electrons and Holes

- Holes travel as do electrons.
- Material can be enriched in holes or electrons by introducing impurities.
- Holes in crystals can be enriched by embedding some boron atoms.
- Electrons in crystals can be enriched by embedding phosphorus atoms.
The Three Regions in a n-p Junction

Formation of a Diffused Junction

A *mask* is a specification of geometric shapes that need to be created on a certain layer. Masks are used to create specific patterns of each material in a sequential manner and create a complex pattern of several layers.

Additional Fabrication Factors

- Scaling
- Parasitic Effects
- Yield Statistics and Fabrication Costs
- Delay Computation
- Noise and Crosstalk
- Power Dissipation
Scaling and Parasitic Effects

The process of shrinking the layout, in which every dimension is multiplied by a factor is called scaling.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Full scaling</th>
<th>CV scaling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensions: width, length, oxide thickness</td>
<td>1/S</td>
<td>1/S</td>

</tr>
<tr>
<td>Current</td>
<td>1/S</td>
<td>S</td>
</tr>
<tr>
<td>Propagation delay</td>
<td>1/S</td>
<td>1/S²</td>
</tr>
</tbody>
</table>

Parasitic effects includes the stray capacitance, the capacitance between the signal paths and ground, and the inherent capacitance of the MOS transistor.
Yield Statistics and Fabrication Costs

Yield of a chip depends on size of the chip and maturity of the process:

\[ C_{ud} = \frac{C_w}{N_d \cdot Y} \]

\( N_d \) = number of dies (chips) fit into a wafer
\( C_{ud} \) = cost of an untested die, \( C_w \) = cost of wafer fabrication,
\( Y \) = probability of a die being functional after processing.

\[ N_d = \pi \frac{(D - \alpha)^2}{4X^2} \]

\( D \) = diameter of the wafer,
\( \alpha \) = useless scrap edge distance of a wafer, \( X \) = chip dimension.
Yield Statistics and Fabrication Costs

\[ Y = (1 - A\delta/c)^c \]

\( Y \) = yield, \( A \) = area of a single chip,
\( \delta \) = defect density, \( c \) = parameter that indicates defect clustering.

\[ N_g = \frac{(X^2 - P \times A_{io})}{A_g} \]

\( N_g \) = number of gates in a single IC,
\( P \) = number of pads on the chip surface, \( A_g \) = area of a logic gate,
\( A_{io} \) = area of an I/O cell.

\[ P = 4(X/S - 1) \]

\( S \) = the minimum pad to pad pitch,
\( P \) = number of pads required to connect the chip to next level of interconnect.
Delay Computation

$$R = \frac{\rho l_c}{h_c w_c}$$

$\rho$=resistivity, $w_c$, $h_c$, and $l_c$

are the width, thickness, and length of the conductor.

$R$=resistance of a uniform slab of conducting material.

$$C = \left[ 1.15 \left( \frac{w_c}{t_o} \right) + 2.80 \left( \frac{h_c}{t_o} \right)^{0.222} \right]$$
$$+ \left[ 0.06 \left( \frac{w_c}{t_o} \right) + 1.66 \left( \frac{h_c}{t_o} \right) - 0.14 \left( \frac{h_c}{t_o} \right)^{0.222} \right] \left( \frac{t_o}{w_{ic}} \right)^{1.34} \epsilon_s \epsilon_o l_c$$

$C$=capacitance of the conductor, $w_{ic}$=spacing of chip interconnections,

$t_o$=thickness of the oxide, $\epsilon_s$=permittivity of free space,

$\epsilon_o$=dielectric constant of the insulator.
Noise Crosstalk

Noise principally stems from resistive and capacitive coupling. Noise margin is defined in terms of two parameters: Low Noise Margin (LNM) and High Noise Margin (HNM).

\[
LNM = \max(V_{IL}) - \max(V_{OL})
\]

\[
HNM = \min(V_{OH}) - \min(V_{IH})
\]

Where \(V_{IL}\) and \(V_{IH}\) are low and high input voltages and \(V_{OL}\) and \(V_{OH}\) are low and high output voltages respectively.

One of the forms of noise is crosstalk, which is a result of mutual capacitance and inductance between neighboring lines.
Power Dissipation

- Temperature must be as uniform as possible over the entire chip surface.
- Heat generated must be efficiently removed from the chip surface.
- A CMOS gate uses 0.003 mW/MHz/gate in ‘off’ state and 0.8 mW/MHz/gate during its operation.
- A ECL system uses 25 mW/gate irrespective of state and operating frequency.
Summary

1. The three types of materials are insulators, conductors, and semiconductors.
2. A VLSI chip consists of several layers of different materials on a silicon wafer.
3. Each layer is defined by a mask.
4. VLSI fabrication process patterns each layer using a mask.
5. Complex VLSI circuits can be developed using basic VLSI devices.
6. Design rules must be followed to allow proper fabrication.
7. Several factors such as scaling, parasitic effects, yield statistics and fabrication Costs, delay computation, noise and crosstalk, and power dissipation play a keyrole in fabrication of VLSI chips.
